Dear AirOps Hiring Team,

AirOps is betting that the brands that win in the AI era are the ones that engineer their content deliberately, not the ones that produce more of it. I have spent the last several years building exactly that kind of system: taking a messy, repetitive knowledge-work process, building an AI workflow around it, and making it repeatable enough that non-technical people could run it themselves. The Solutions Architect role is the job I have been doing in a different vertical. I am writing because I want to do it in yours.

At Smarter Technologies, I built a 22-skill AI platform using Claude Code as the agentic layer. Not a chatbot. The primary interface through which all sales engineering work got executed. I designed the prompt architecture, wrote the Python integration scripts, built the co-work interface, and shipped 943 commits over seven months while simultaneously managing \$31.8M in active enterprise pipeline across 61 deals. Two people. Sixty-two percent of total company pipeline. The force multiplier was real. When team members started messaging me on Slack to query my agent on their behalf, I ported the highest-impact skills to a shared platform so the whole team could invoke them directly without writing a single prompt. That motion, build it internally until it works, then productize it so non-technical users can run it themselves, is what I understand AirOps to be describing in this role.

Earlier, at Action Network, I built the "Value Clicks" model: a probability-weighted score for every on-page user action based on its empirically measured likelihood of leading to affiliate activation or subscription. The metric became the company-wide north star. Both content and product aligned their roadmaps around it. But what I am most proud of from that period is not the model. It is what we did with it. I met weekly with the Chief Content Officer to translate data signals into actual editorial decisions: which sports to lean into, which content formats drove conversion rates up, where we were losing audience we should have been capturing. I worked directly with editors on coverage calendars and individual writers on SEO structure, headline strategy, and publication timing. The company grew affiliate revenue 270% in the 12 months after launch. That outcome came from data-to-decision translation, not from the model alone. I think that is what AirOps means when they talk about turning content performance data into competitive advantage.

The production AI systems work is where I push hardest. At Thoughtful AI, I built the company's first GenAI system: a hybrid-RAG eligibility engine that matched unstructured free-text coverage limitations to correct billing determinations using OpenAI embeddings and in-context learning. It hit 95% accuracy within two days on a live production workflow. I built labeled holdout datasets, precision and recall tracking by failure category, and regression tests that ran before every model or prompt change. The eval infrastructure was the reason accuracy held under real-world variation. The approach was presented to

the board and replicated across three additional automations within a month. My design principle is consistent: use AI where it genuinely adds value, write deterministic code everywhere else. That is what makes AI workflows work in production instead of just in demos.

AirOps raised \$40M in November 2025 to help brands get found and stay found as discovery shifts from search engines to AI assistants. The Solutions Architect is the person who builds those workflows internally, turns the best ones into templates and agents that customers can run, monitors the metrics that tell you what is working, and closes the feedback loop. I have been doing that end-to-end for three years in healthcare. I am ready to bring it to growth and marketing teams, where the underlying AI workflow patterns are the same and the domain is genuinely new to me. I would welcome the opportunity to talk about what that looks like in practice.

Sincerely,

**Dan Mathieson**
